

GRIDALIGN

Coordination Opportunity Report

Georgia Power

Callaway Road - Thomson Primary 500 kV

Distance between closest known points: 20.05 km

Dominion Energy South Carolina

Modoc - McCormick 115/46 kV Rebuild

PROJECTS

- Project A: Callaway Road - Thomson Primary 500 kV, located in Georgia (Columbia and McDuffie counties). The operating utility is not stated in the provided data.
- Project B: Modoc - McCormick 115/46 kV Rebuild, located in McCormick County, South Carolina. The operating utility is not stated in the provided data.

WHY GRIDALIGN FLAGGED THIS PAIR

The closest known points between the two projects are separated by 20.05 km. This places them in GridAlign's under 40 km distance tier, indicating potential opportunities for regional mobilization and high-level construction planning.

GEOGRAPHIC ANALYSIS

At a distance of 20.05 km across the Georgia-South Carolina border area, the projects are too far apart to share immediate right-of-way, local access roads, or joint staging yards. However, the proximity is close enough that regional construction planning, contractor sourcing, and specialized transmission equipment movements could potentially be coordinated across this shared regional footprint.

TIMELINE ANALYSIS

Project A has an identified start date of Spring 2027, with no completion date specified. Project B has an estimated completion date of December 31, 2029, with no start date specified. Because both projects involve activity spanning the 2027 to 2029 timeframe, their active construction windows could potentially overlap. However, timeline compatibility cannot be fully confirmed due to the incomplete schedule details.

COORDINATION OPPORTUNITIES

- Contractor sharing: Regional high-voltage transmission contractors could potentially be engaged across both projects.
- Specialized equipment sharing: Specialized line construction apparatus, such as heavy tensioners, pullers, or cranes, may be coordinated or sequenced between sites if these resources are required.

- Mobilization sequencing: Equipment delivery and mobilization routes could potentially be staged sequentially across the region to minimize transit costs.
- Outage timing coordination: Regional grid operators may be able to align transmission outage windows to prevent simultaneous capacity restrictions across the regional network.

POTENTIAL BENEFITS

- Potential reduction in equipment transport and duplicate mobilization expenses if regional contractors or specialty machinery serve both sites.
- Minimized regional transmission bottlenecks through coordinated construction outage planning.
- Improved workforce availability if contractor schedules are aligned in advance.

RISKS AND LIMITATIONS

- Scope and technical incompatibility: Project A involves new 500 kV lines and substation construction, whereas Project B is a 115/46 kV line rebuild. These distinct voltage classes may require different conductor-handling equipment, hardware, and crew certifications.
- Jurisdictional separation: The projects are located in different states (Georgia and South Carolina) and likely operate under separate utility and regulatory jurisdictions.
- Missing schedule data: Incomplete start and end dates prevent confirmation of whether active construction will coincide.

FINAL ASSESSMENT

MEDIUM

Meaningful coordination appears plausible regarding regional contractor procurement, equipment mobilization, and regional outage planning within a 20.05 km distance, but important uncertainty remains regarding schedule alignment, interstate jurisdictional barriers, and differing voltage-class technical requirements.

RECOMMENDED NEXT STEP

Utility planners should arrange an introductory coordination call to share detailed construction schedules and evaluate regional transmission outage requirements for 2027 through 2029.
