Okatie - McIntosh 115kV Tie: Add Series Reactor

PROJECTS

- Plant McIntosh Natural Gas Upgrades: Georgia Power (capacity expansion adding 268 MW of natural gas generating capacity).
- Okatie - McIntosh 115kV Tie: Add Series Reactor: Utility sponsor not explicitly named, associated with South Carolina planning (construct Deerfield Switching Station and install a 9% series reactor on the Okatie - McIntosh 115kV tie line).

WHY GRIDALIGN FLAGGED THIS PAIR

The closest known coordinates are separated by 23.94 km, placing them in the under 40 km category. Additionally, both projects reference the McIntosh electrical node or facility area.

GEOGRAPHIC ANALYSIS

At 23.94 km across the Georgia-South Carolina state border, the projects are too far apart for shared access roads or work zones. However, this regional distance may allow project teams to coordinate high-voltage electrical planning, regional contractor procurement, and mobilization of specialized heavy equipment.

TIMELINE ANALYSIS

- Plant McIntosh Natural Gas Upgrades: Start and end dates are not provided in the source records.
- Okatie - McIntosh 115kV Tie: Estimated completion date is December 31, 2028; start date is not specified.

Timeline compatibility cannot be fully confirmed due to missing schedule data for the generation upgrades and missing start timing for the switching station.

COORDINATION OPPORTUNITIES

- Outage timing and grid operational planning: Because Project B affects the Okatie - McIntosh 115kV tie line and Project A expands generation at Plant McIntosh, the utilities could potentially coordinate transmission line outages and generation interconnection testing to avoid reliability conflicts.

- Regional contractor sharing: The project sponsors may be able to engage shared regional electrical contractors or testing and commissioning engineers.
- Specialized equipment logistics: If heavy transport, high-voltage test equipment, or large cranes are required around the same period, mobilization efforts could potentially be sequenced across both sites.

POTENTIAL BENEFITS

- Improved electrical grid stability by aligning generation commissioning with transmission line modifications.
- Reduced duplicate mobilization costs if regional contractors or testing resources can serve both locations.
- Minimized operational disruption across the regional intertie connecting Georgia and South Carolina.

RISKS AND LIMITATIONS

- Incomplete timeline data prevents verifying whether on-site construction windows will overlap.
- The projects involve different work scopes, with one focusing on natural gas generation expansion and the other on substation construction and reactor installation.
- Cross-state jurisdiction (Georgia and South Carolina) and potentially separate operating utilities could introduce administrative barriers to joint procurement or scheduling.

FINAL ASSESSMENT

MEDIUM

A direct electrical relationship appears plausible given the shared McIntosh intertie reference, and geographic distance is under 24 km. However, significant schedule uncertainty and cross-border utility boundaries keep this opportunity at a medium level.

RECOMMENDED NEXT STEP

Utility planners should convene an interconnection and outage coordination meeting to verify whether the 2028 tie-line reactor project impacts or aligns with the Plant McIntosh capacity expansion schedule.
